## 1.1 About

oscode is a C++ tool with a Python interface that solves **oscillatory ordinary differential equations** efficiently. It is designed to deal with equations of the form

$$\ddot{x}(t) + 2\gamma(t)\dot{x}(t) + \omega^2(t)x(t) = 0,$$

where  $\gamma(t)$  and  $\omega(t)$  can be given as arrays.

oscode makes use of an analytic approximation of  $x(t)$  embedded in a stepping procedure to skip over long regions of oscillations, giving a reduction in computing time. The approximation is valid when the frequency  $\omega(t)$  changes slowly relative to the timescales of integration, it is therefore worth applying when this condition holds for at least some part of the integration range.

For the details of the numerical method used by oscode, see the Citations section.

## 1.2 Installation

### 1.2.1 Dependencies

Basic requirements for using the C++ interface:

- C++11 or later
- [Eigen](#) (a header-only library included in this source)

The strictly necessary Python dependencies are automatically installed when you use *pip* or the *setup.py*. They are:

- [numpy](#)

The *optional* dependencies are:

- **for tests**
  - [scipy](#)
  - [pytest](#)
- **for examples/plotting**
  - [matplotlib](#)
  - [scipy](#)
- **for generating offline documentation**
  - [sphinx](#)
  - [doxygen](#)
  - [breathe](#)
  - [exhale](#)

## 1.2.2 Python

pyoscode can be installed via pip

```
pip install pyoscode
```

or via the setup.py

```
git clone https://github.com/fruzsinaagocs/oscode
cd oscode
python setup.py install --user
```

You can then import pyoscode from anywhere. Omit the `--user` option if you wish to install globally or in a virtual environment. If you have any difficulties, check out the [FAQs](#) section below.

You can check that things are working by running `tests/` (also ran by Travis continuous integration):

```
pytest tests/
```

## 1.2.3 C++

oscode is a header-only C++ package, it requires no installation.

```
git clone https://github.com/fruzsinaagocs/oscode
```

and then include the relevant header files in your C++ code:

```
#include "solver.hpp"
#include "system.hpp"
```

## 1.3 Quick start

Try the following quick examples. They are available in the [examples](#).

### 1.3.1 Python

**Introduction to pyoscode**

**Cosmology examples**

### 1.3.2 C++

**Introduction to oscode** *examples/burst.cpp*

**To plot results from *burst.cpp*** *examples/plot\_burst.py*

To compile and run:

```
g++ -g -Wall -std=c++11 -c -o burst.o burst.cpp
g++ -g -Wall -std=c++11 -o burst burst.o
./burst
```

## 1.4 Documentation

Documentation is hosted at [readthedocs](#).

To build your own local copy of the documentation you can run:

```
cd pyoscode/docs
make html
```

## 1.5 Citation

If you use oscode to solve equations for a publication, please cite:

- Efficient method for solving highly oscillatory ordinary differential equations with applications to physical systems,
- Dense output for highly oscillatory numerical solutions

## 1.6 Contributing

Any comments and improvements to this project are welcome. You can contribute by:

- Opening and [issue](#) to report bugs and propose new features.
- Making a pull request.

## 1.7 Further help

You can get help by submitting an issue or posting a message on [Gitter](#).

## 1.8 FAQs

### 1.8.1 Installation

#### 1. Eigen import errors:

```
pyoscode/_pyoscode.hpp:6:10: fatal error: Eigen/Dense: No such file or directory
#include <Eigen/Dense>
         ^~~~~~
```

Try explicitly including the location of your Eigen library via the `CPLUS_INCLUDE_PATH` environment variable, for example:

```
CPLUS_INCLUDE_PATH=/usr/include/eigen3 python setup.py install --user  
# or  
CPLUS_INCLUDE_PATH=/usr/include/eigen3 pip install pyoscode
```

where `/usr/include/eigen3` should be replaced with your system-specific eigen location.

## 1.9 Thanks

Many thanks to **Will Handley**, **Lukas Hergt**, **Anthony Lasenby**, and **Mike Hobson** for their support and advice regarding the algorithm behind *oscode*. There are many packages without which some part of *oscode* (e.g. testing and examples) wouldn't run as nicely and smoothly, thank you all developers for making and maintaining these open-source projects. A special thanks goes to the devs of *exhale* for making the beautiful C++ documentation possible.

## 1.10 Changelog

- **1.0.0: current version**
  - Dense output
  - Arrays for frequency and damping term need not be evenly spaced
  - Automatic C++ documentation on readthedocs
  - Eigen included in source for pip installability
  - First pip release :)
- **0.1.2:**
  - Bug that occurred when beginning and end of integration coincided corrected
- **0.1.1:**
  - Automatic detection of direction of integration
- **0.1.0:**
  - Memory leaks at python interface fixed
  - C++ documentation added

## PYOSCODE

`pyoscode.solve`(*ts, ws, gs, ti, tf, x0, dx0, t\_eval=[], logw=False, logg=False, order=3, rtol=0.0001, atol=0.0, h=None, full\_output="", even\_grid=False, check\_grid=False*)

Solve a differential equation with the RKWKB method.

### Parameters

**ts: numpy.ndarray [float] or list [float]** An array of real numbers representing the values of the independent variable at which the frequency and friction term are evaluated.

**ws: numpy.ndarray [complex] or list [complex]** An array-like object of real or complex numbers, representing the values of frequency  $w$  at the points given in *ts*.

**gs: numpy.ndarray [complex] or list [complex]** An array-like object of real or complex numbers representing the values of the friction term  $g$  at the points given in *ts*.

**ti,tf: float** Start and end of integration range.

**x0, dx0: complex** Initial values of the dependent variable and its derivative.

**t\_eval: numpy.ndarray [float] or list [float]** An array of times where the solution is to be returned.

**logw, logg: boolean, optional** If true, the array of frequencies and friction values, respectively, will be exponentiated (False, False by default).

**order: int, optional** Order of WKB approximation to use, 3 (the highest value) by default.

**rtol, atol: float, optional** Relative and absolute tolerance of the solver,  $1e-4$  and 0 by default. Note that *atol* at the moment is not implemented.

**h: float, optional** Size of the initial step, 1 by default.

**full\_output: str, optional** If given, the return dictionary will be written to a file with the supplied name.

**even\_grid: boolean, optional** False by default. Set this to True if the *ts* array is evenly spaced for faster interpolation.

**check\_grid: boolean, optional** False by default. If True, the fineness of the *ws*, *gs* grids will be checked based on how accurate linear interpolation would be on them, and a warning will be issued if this accuracy is deemed too low. It's a good idea to set this to True when solving an equation for the first time.

### Returns

A dictionary with the following keywords and values:

**sol: list [complex]** A list containing the solution evaluated at timepoints listed under the 't' keyword.

**dsol: list [complex]** A list containing the first derivative of the solution evaluated at timepoints listed under the 't' keyword.

**t: list [float]** Contains the values of the independent variable where the solver stepped, i.e. evaluated the solution at. This is not determined by the user, rather these are the internal steps the solver naturally takes when integrating.

**types: list [float]** A list of True/False values corresponding to the step types the solver chose at the timepoints listed under the keyword 't'. If True, the step was WKB, and RK otherwise.

**x\_eval: list [complex]** Values of the solution at the points specified in t\_eval.

**dx\_eval: list [complex]** Values of the derivative of the solution at the points specified in t\_eval.

## 1 USING THE C++ INTERFACE (OSCODE)

### 3.1 1.1 Overview

This documentation illustrates how one can use `oscode` via its C++ interface. Usage of `oscode` involves

- defining an equation to solve,
- solving the equation,
- and extracting the solution and other statistics about the run.

The next sections will cover each of these. For a complete reference, see the [C++ interface reference](#) page, and for examples see the [examples](#) directory on GitHub.

### 3.2 1.2 Defining an equation

The equations `oscode` can be used to solve are of the form

$$\ddot{x}(t) + 2\gamma(t)\dot{x}(t) + \omega^2(t)x(t) = 0,$$

where  $x(t)$ ,  $\gamma(t)$ ,  $\omega(t)$  can be complex. We will call  $t$  the independent variable,  $x$  the dependent variable,  $\omega(t)$  the frequency term, and  $\gamma(t)$  the friction or first-derivative term.

Defining an equation is via

- giving the frequency  $\omega(t)$ ,
- giving the first-derivative term  $\gamma(t)$ ,

Defining the frequency and the first-derivative term can either be done by giving them as **functions explicitly**, or by giving them as **sequences** evaluated on a grid of  $t$ .

#### 3.2.1 1.2.1 $\omega$ and $\gamma$ as explicit functions

If  $\omega$  and  $\gamma$  are closed-form functions of time, then define them as

```
#include "solver.hpp" // de_system, Solution defined in here

std::complex<double> g(double t){
    return 0.0;
};
```

(continues on next page)

(continued from previous page)

```
std::complex<double> w(double t){
    return std::pow(9999,0.5)/(1.0 + t*t);
};
```

Then feed them to the solver via the `de_system` class:

```
de_system sys(&w, &g);
Solution solution(sys, ...) // other arguments left out
```

### 3.2.2 1.2.2 $\omega$ and $\gamma$ as time series

Sometimes  $\omega$  and  $\gamma$  will be results of numerical integration, and they will have no closed-form functional form. In this case, they can be specified on a grid, and `oscode` will perform linear interpolation on the given grid to find their values at any timepoint. Because of this, some important things to **note** are:

- `oscode` will assume the grid of timepoints  $\omega$  and  $\gamma$  are **not evenly spaced**. If the grids are evenly sampled, set `even=true` in the call for `de_system()`, this will speed linear interpolation up significantly.
- The timepoints grid needs to be **monotonically increasing**.
- The timepoints grid needs to **include the range of integration** ( $t_i, :math:t_f$ ).
- The grids for the timepoints, frequencies, and first-derivative terms have to be the **same size**.
- The speed/efficiency of the solver depends on how accurately it can carry out numerical integrals of the frequency and the first-derivative terms, therefore the **grid fineness** needs to be high enough. (Typically this means that linear interpolation gives a  $\omega(t)$  value that is accurate to 1 part in  $10^6$  or so.) If you want `oscode` to check whether the grids were sampled finely enough, set `check_grid=true` in the call for `de_system()`.

To define the grids, use any array-like container which is **contiguous in memory**, e.g. an `Eigen::Vector`, `std::array`, `std::vector`:

```
#include "solver.hpp" // de_system, Solution defined in here

// Create a fine grid of timepoints and
// a grid of values for w, g
N = 10000;
std::vector<double> ts(N);
std::vector<std::complex<double>> ws(N), gs(N);

// Fill up the grids
for(int i=0; i<N; i++){
    ts[i] = i;
    ws[i] = std::sqrt(i);
    gs[i] = 0.0;
}
```

They can then be given to the solver again by feeding a pointer to their underlying data to the `de_system` class:

```
de_system sys(ts.data(), ws.data(), gs.data());
Solution solution(sys, ...) // other arguments left out
```

Often  $\omega$  and  $\gamma$  are much easier to perform linear interpolation on once taken natural log of. This is what the optional `islogw` and `islogg` arguments of the overloaded `de_system::de_system()` constructor are for:

```

#include "solver.hpp" // de_system, Solution defined in here

// Create a fine grid of timepoints and
// a grid of values for w, g
N = 10000;
std::vector<double> ts(N);
std::vector<std::complex<double> logws(N), gs(N); // Note the log!

// Fill up the grids
for(int i=0; i<N; i++){
    ts[i] = i;
    logws[i] = 0.5*i;
    gs[i] = 0.0; // Will not be logged
}

// We want to tell de_system that w has been taken natural log of, but g
// hasn't. Therefore islogw=true, islogg=false:
de_system sys(ts.data(), logws.data(), gs.data(), true, false);
Solution solution(sys, ... ) // other arguments left out

```

### 1.2.2.1 DIY interpolation

For some problems, linear interpolation of  $\omega$  and  $\gamma$  (or their natural logs) might simply not be enough.

For example, the user could carry out cubic spline interpolation and feed  $\omega$  and  $\gamma$  as functions to `de_system`.

Another example for wanting to do (linear) interpolation outside of `oscode` is when `Solution.solve()` is ran in a loop, and for each iteration a large grid of  $\omega$  and  $\gamma$  is required, depending on some parameter. Instead of generating them over and over again, one could define them as functions, making use of some underlying vectors that are independent of the parameter we iterate over:

```

// A, B, and C are large std::vectors, same for each run
// k is a parameter, different for each run
// the grid of timepoints w, g are defined on starts at tstart, and is
// evenly spaced with a spacing tinc.

// tstart, tinc, A, B, C defined here

std::complex<double> g(double t){
    int i;
    i=int((t-tstart)/tinc);
    std::complex<double> g0 = 0.5*(k*k*A[i] + 3.0 - B[i] + C[i]*k);
    std::complex<double> g1 = 0.5*(k*k*A[i+1] + 3.0 - B[i+1] + C[i+1]*k);
    return (g0+(g1-g0)*(t-tstart-tinc*i)/tinc);
};

```

### 3.3 1.3 Solving an equation

Once the equation to be solver has been defined as an instance of the `de_system` class, the following additional information is necessary to solve it:

- initial conditions,  $x(t_i)$  and  $\dot{x}(t_f)$ ,
- the range of integration, from  $t_i$  and  $t_f$ ,
- (optional) set of timepoints at which dense output is required,
- (optional) order of WKB approximation to use, `order=3`,
- (optional) relative tolerance, `rtol=1e-4`,
- (optional) absolute tolerance `atol=0.0`,
- (optional) initial step `h_0=1`,
- (optional) output file name `full_output=""`,

**Note** the following about the optional arguments:

- `rtol`, `atol` are tolerances on the local error. The global error in the solution is not guaranteed to stay below these values, but the error per step is. In the RK regime (not oscillatory solution), the global error will rise above the tolerance limits, but in the WKB regime, the global error usually stagnates.
- The initial step should be thought of as an initial estimate of what the first stepsize should be. The solver will determine the largest possible step within the given tolerance limit, and change `h_0` if necessary.
- The full output of `solve()` will be written to the filename contained in `full_output`, if specified.

Here's an example to illustrate usage of all of the above variables:

```
#include "solver.hpp" // de_system, Solution defined in here

// Define the system
de_system sys(...) // For args see previous examples

// Necessary parameters:
// initial conditions
std::complex<double> x0=std::complex<double>(1.0,1.0), dx0=0.0;
// range of integration
double ti=1.0, tf=100.0;

// Optional parameters:
// dense output will be required at the following points:
int n = 1000;
std::vector t_eval(n);
for(int i=0; i<n; i++){
    t_eval[i] = i/10.0;
}
// order of WKB approximation to use
int order=2;
// tolerances
double rtol=2e-4, atol=0.0;
// initial step
double h0 = 0.5;
// write the solution to a file
```

(continues on next page)

(continued from previous page)

```
std::string outfile="output.txt";

Solution solution(sys, x0, dx0, ti, tf, t_eval.data(), order, rtol, atol, h0, outfile);
// Solve the equation:
solution.solve()
```

Here, we've also called the `solve()` method of the `Solution` class, to carry out the integration. Now all information about the solution is in `solution` (and written to `output.txt`).

### 3.4 1.4 Using the solution

Let's break down what `solution` contains (what `Solution.solve()` returns). An instance of a `Solution` object is returned with the following attributes:

- `times` [std::list of double]: timepoints at which the solution was determined. These are **not** supplied by the user, rather they are internal steps that the solver has taken. The list starts with  $t_i$  and ends with  $t_f$ , these points are always guaranteed to be included.
- `sol` [std::list of std::complex<double>]: the solution at the timepoints specified in `times`.
- `dsol` [std::list of std::complex<double>]: first derivative of the solution at timepoints specified in `times`.
- `wkbs` [std::list of int/bool]: types of steps taken at each timepoint in `times`. **1** if the step was WKB, **0** if it was RK.
- `ssteps` [int]: total number of accepted steps.
- `totsteps` [int]: total number of attempted steps (accepted + rejected).
- `wkbsteps` [int]: total number of successful WKB steps.
- `x_eval` [std::list of std::complex<double>]: dense output, i.e. the solution evaluated at the points specified in the `t_eval` optional argument
- `dx_eval` [std::list of std::complex<double>]: dense output of the derivative of the solution, evaluated at the points specified in `t_eval` optional argument.

## 4.1 Class Hierarchy

## 4.2 File Hierarchy

## 4.3 Full API

### 4.3.1 Classes and Structs

#### Template Struct `LinearInterpolator`

- Defined in file `__home_docs_checkouts_readthedocs.org_user_builds_oscode_checkouts_latest_include_interpolator.hpp`

#### Struct Documentation

```
template<typename X = double*, typename Y = std::complex<double>*, typename InputIt_x = double*>
```

```
struct LinearInterpolator
```

#### Public Functions

```
inline LinearInterpolator()
```

```
inline LinearInterpolator(X x, Y y, int even)
```

```
inline void set_interp_start(InputIt_x x_start)
```

```
inline void set_interp_bounds(InputIt_x lower_it, InputIt_x upper_it)
```

```
inline void update_interp_bounds()
```

```
inline void update_interp_bounds_reverse()
```

```
inline std::complex<double> operator()(double x)
```

```
inline std::complex<double> expit(double x)
```

```
inline int check_grid_fineness(int N)
```

## Public Members

```
int sign_
```

```
double xstart
```

```
double dx
```

```
X x_
```

```
Y y_
```

```
int even_
```

```
InputIt_x x_lower_bound
```

```
InputIt_x x_upper_bound
```

```
InputIt_x x_lower_it
```

```
InputIt_x x_upper_it
```

```
InputIt_x x0_it
```

```
double x_lower
```

```
double x_upper
```

double **h**

std::complex<double> **y\_lower**

std::complex<double> **y\_upper**

## Class `de_system`

- Defined in file `__home_docs_checkouts_readthedocs.org_user_builds_oscode_checkouts_latest_include_system.hpp`

## Class Documentation

class `de_system`

### Public Functions

template<typename **X**, typename **Y**, typename **Z**, typename **X\_it**>  
**de\_system**(**X** &ts, **Y** &ws, **Z** &gs, **X\_it** x\_it, int size, bool isglgw = false, bool islogg = false, int even = 0, int  
check\_grid = 0)

Constructor for the case of the user having defined the frequency and damping terms as sequences

**de\_system**(std::complex<double> (\*)(double, void\*), std::complex<double> (\*)(double, void\*), void\*)

**de\_system**(std::complex<double> (\*)(double), std::complex<double> (\*)(double))

**de\_system**()

Default constructor

### Public Members

std::function< std::complex< double >double>> **w**

std::function< std::complex< double >double>> **g**

*LinearInterpolator* **Winterp**

*LinearInterpolator* **Ginterp**

bool **islogg\_**

bool `islogw_`

bool `grid_fine_enough` = 1

bool `is_interpolated`

## Class RKSolver

- Defined in file `__home_docs_checkouts_readthedocs.org_user_builds_oscode_checkouts_latest_include_rksolver.hpp`

## Class Documentation

### class `RKSolver`

Class that defines a 4 and 5th order Runge-Kutta method.

This is a “bespoke” Runge-Kutta formula based on the nodes used in 5th and 6th order Gauss-Lobatto integration, as detailed in [1].

[1] Agocs, F. J., et al. “Efficient Method for Solving Highly Oscillatory Ordinary Differential Equations with Applications to Physical Systems.” *Physical Review Research*, vol. 2, no. 1, 2020, doi:10.1103/physrevresearch.2.013030.

## Public Functions

### `RKSolver()`

Callable that gives the frequency term in the ODE at a given time

Default constructor.

### `RKSolver(de_system &de_sys)`

Constructor for the `RKSolver` class. It sets up the Butcher tableaus for the two Runge-Kutta methods (4th and 5th order) used.

**Parameters** `de_sys[in]` – the system of first-order equations defining the second-order ODE to solve.

`Eigen::Matrix<std::complex<double>, 2, 2>` `step`(`std::complex<double>`, `std::complex<double>`, `double`, `double`)

`Eigen::Matrix<std::complex<double>, 1, 2>` `f`(`double t`, `const Eigen::Matrix<std::complex<double>, 1, 2> &y`)

Turns the second-order ODE into a system of first-order ODEs as follows:

$$\begin{aligned}y &= [x, \dot{x}], \\y[0] &= y[1], \\y[1] &= -\omega^2(t)y[0] - 2\gamma(t)y[1].\end{aligned}$$

**Parameters**

- **t[in]** – time  $t$
- **y[in]** – vector of unknowns  $y = [x, \dot{x}]$

**Returns** a vector of the derivative of  $y$

Eigen::Matrix<std::complex<double>, 1, 2> **dense\_point**(std::complex<double> x, std::complex<double> dx, const Eigen::Matrix<std::complex<double>, 6, 2> &k5)

void **dense\_step**(double t0, double h0, std::complex<double> y0, std::complex<double> dy0, const std::list<double> &dots, std::list<std::complex<double>> &doxs, std::list<std::complex<double>> &dodxs)

**Public Members**

*de\_system* \***de\_sys\_**  
Defines the ODE

Eigen::Matrix<std::complex<double>, 6, 1> **ws**  
6 values of the frequency term per step, evaluated at the nodes of 6th order Gauss-Lobatto quadrature

Eigen::Matrix<std::complex<double>, 6, 1> **gs**  
6 values of the friction term per step, evaluated at the nodes of 6th order Gauss-Lobatto quadrature

Eigen::Matrix<std::complex<double>, 5, 1> **ws5**  
5 values of the frequency term per step, evaluated at the nodes of 5th order Gauss-Lobatto quadrature

Eigen::Matrix<std::complex<double>, 5, 1> **gs5**  
5 values of the friction term per step, evaluated at the nodes of 5th order Gauss-Lobatto quadrature

Eigen::Matrix<std::complex<double>, 6, 2> **k5**

Eigen::Matrix<std::complex<double>, 7, 2> **k\_dense**

Eigen::Matrix<double, 7, 4> **P\_dense**

## Class Solution

- Defined in file `__home_docs_checkouts_readthedocs.org_user_builds_oscode_checkouts_latest_include_solver.hpp`

## Class Documentation

### class **Solution**

A class to store all information related to a numerical solution run.

### Public Functions

**Solution**(*de\_system* &de\_sys, std::complex<double> x0, std::complex<double> dx0, double t\_i, double t\_f, int o = 3, double r\_tol = 1e-4, double a\_tol = 0.0, double h\_0 = 1, const char \*full\_output = "")  
Constructor for when dense output was not requested. Sets up solution of the ODE.

#### Parameters

- **de\_sys** – [in] *de\_system* object carrying information about the ODE being solved
- **x0**, **dx0** – [in] initial conditions for the ODE,  $x(t)$ ,  $\frac{dx}{dt}$  evaluated at the start of the integration range
- **t\_i** – [in] start of integration range
- **t\_f** – [in] end of integration range
- **o** – [in] order of WKB approximation to be used
- **r\_tol** – [in] (local) relative tolerance
- **a\_tol** – [in] (local) absolute tolerance
- **h\_0** – [in] initial stepsize to use
- **full\_output** – [in] file name to write results to

template<typename **X** = double>

**Solution**(*de\_system* &de\_sys, std::complex<double> x0, std::complex<double> dx0, double t\_i, double t\_f, const **X** &do\_times, int o = 3, double r\_tol = 1e-4, double a\_tol = 0.0, double h\_0 = 1, const char \*full\_output = "")

Constructor for when dense output was requested. Sets up solution of the ODE.

#### Parameters

- **de\_sys** – [in] *de\_system* object carrying information about the ODE being solved
- **x0**, **dx0** – [in] initial conditions for the ODE,  $x(t)$ ,  $\frac{dx}{dt}$  evaluated at the start of the integration range
- **t\_i** – [in] start of integration range
- **t\_f** – [in] end of integration range
- **do\_times** – [in] timepoints at which dense output is to be produced. Doesn't need to be sorted, and duplicated are allowed.
- **o** – [in] order of WKB approximation to be used
- **r\_tol** – [in] (local) relative tolerance
- **a\_tol** – [in] (local) absolute tolerance

- **h\_0** – [in] initial stepsize to use
- **full\_output** – [in] file name to write results to

void **solve()**

Function to solve the ODE  $\ddot{x} + 2\gamma(t)\dot{x} + \omega^2(t)x = 0$  for  $x(t)$ ,  $\frac{dx}{dt}$ .

While solving the ODE, this function will populate the [Solution](#) object with the following results:

## Public Members

*RKSolver* **rksolver**

Object to call RK steps

int **ssteps**

Successful, total attempted, and successful WKB steps the solver took, respectively

int **totsteps**

int **wkbsteps**

std::list<std::complex<double>> **sol**

Lists to contain the solution and its derivative evaluated at internal points taken by the solver (i.e. not dense output) after a run

std::list<std::complex<double>> **dsol**

std::list<double> **times**

List to contain the timepoints at which the solution and derivative are internally evaluated by the solver

std::list<bool> **wkbs**

List to contain the “type” of each step (RK/WKB) taken internally by the solver after a run

std::list<double> **dotimes**

Lists to contain the timepoints at which dense output was evaluated. This list will always be sorted in ascending order (with possible duplicates), regardless of the order the timepoints were specified upon input.

std::list<std::complex<double>> **dosol**

Lists to contain the dense output of the solution and its derivative

std::list<std::complex<double>> **dodsol**

std::list<double>::iterator **dotit**

Iterator to iterate over the dense output timepoints, for when these need to be written out to file

## Class WKBSolver

- Defined in file `__home_docs_checkouts_readthedocs.org_user_builds_oscode_checkouts_latest_include_wkbsolver.hpp`

## Inheritance Relationships

## Derived Types

- `public WKBSolver1` (*Class WKBSolver1*)
- `public WKBSolver2` (*Class WKBSolver2*)
- `public WKBSolver3` (*Class WKBSolver3*)

## Class Documentation

### class **WKBSolver**

Class to carry out WKB steps of varying orders.

Subclassed by *WKBSolver1*, *WKBSolver2*, *WKBSolver3*

### Public Functions

**WKBSolver**()

**WKBSolver**(*de\_system* &de\_sys, int order)

Eigen::Matrix<std::complex<double>, 3, 2> **step**(std::complex<double> x0, std::complex<double> dx0, double t0, double h0, const Eigen::Matrix<std::complex<double>, 6, 1> &ws, const Eigen::Matrix<std::complex<double>, 6, 1> &gs, const Eigen::Matrix<std::complex<double>, 5, 1> &ws5, const Eigen::Matrix<std::complex<double>, 5, 1> &gs5)

Computes a WKB step of a given order and returns the solution and its local error estimate.

#### Parameters

- **x0[in]** – value of the solution  $x(t)$  at the start of the step
- **dx0[in]** – value of the derivative of the solution  $\frac{dx}{dt}$  at the start of the step
- **t0[in]** – value of independent variable (time) at the start of the step
- **h0[in]** – size of the step (solution will be given at t+t0)
- **ws[in]** – vector of 6 evaluations of the frequency term at the Gauss-Lobatto nodes, this is necessary for Gauss-Lobatto integration, which in turn is needed to calculate the WKB series
- **gs[in]** – vector of 6 evaluations of the friction term
- **ws5[in]** – vector of 5 evaluations of the friction term at the nodes of 5th order Gauss-Lobatto quadrature, this is needed to compute the error on Gauss-Lobatto quadrature, and in turn the WKB series

- **gs5[in]** – vector of 5 evaluations of the friction term

**Returns** a matrix, whose rows are:

- $x, \dot{x}$  at  $t_0+h_0$  as an  $n$ th order WKB estimate
- $\Delta_{\text{trunc}}x, \Delta_{\text{trunc}}\dot{x}$  at  $t_0+h_0$ , defined as the difference between an  $n$ th and  $(n-1)$ th order WKB estimate
- $\Delta_{\text{int}}x, \Delta_{\text{int}}\dot{x}$  at  $t_0+h_0$ , defined as the local error coming from those terms in the WKB series that involved numerical integrals

void **dense\_step**(double t0, const std::list<double> &dots, std::list<std::complex<double>> &doxs, std::list<std::complex<double>> &dodxs)

Computes dense output at a set of timepoints within a step.

**Parameters**

- **t0[in]** – value of independent variable (time) at the start of the step
- **dots[in]** – sequence of timepoints at which dense output is to be generated
- **doxs[in, out]** – dense output for the solution  $x(t)$
- **dodxs[in, out]** – dense output for the derivative of the solution  $\dot{x}$

Eigen::Matrix<double, 6, 1> **dense\_weights\_6**(double t)

Eigen::Matrix<double, 6, 1> **dense\_weights\_derivs\_6**(double t)
